Cosmic metal enrichment by the first galaxies

Andrea Pallottini†

in collaboration with A. Ferrara, S. Gallerani, S. Salvadori, V. D’Odorico

†: Ph.D Student
expected date of defense: fall 2015
currently looking for a position
Key questions:

1. Which are the dominant sources of metal enrichment?
2. What is the cosmic metal enrichment history?
3. What is the link between cosmic enrichment and reionization?
4. How does feedback regulate the galaxy-IGM interplay?
Simulating Cosmic Metal Enrichment

Pallottini et. al 2014a (P14)

- WMAP7 cosmology \cite{Larson2011}
- AMR code RAMSES \cite{Teyssier2002}
- volume \((10 \text{ Mpc} \, h^{-1})^3\)
- \(z_{\text{ini}} = 99, \, z_{\text{end}} = 4\)
- DM resolution \(M_{\text{dm}} \approx 5 \times 10^5 M_\odot\)
- AMR resolution \(\approx [20 - 1] \text{ kpc} \, h^{-1}\)
- UV background \cite{Haardt2012}
- Star formation mimicking S-K relation \cite{Dubois2008}
- Thermal SN feedback \cite{Hopkins2012}
- Yields and return fractions (Pop II & Pop III)

Comparison with observations
Lack of evolution of the HI absorption profile?

analytical model at $z = 0$ (calibrated at $z = 4$)

$z \sim 0$ Liang&Chen 2014 (and errorbars), $z \sim 2$ Steidel et al. 2010,
model by Chen et al. (1998,2001), synthetic spectra at $z = 4$
Conclusions

1. By $z = 6$ a galactic mass-metallicity relation is established. For galaxy with stellar mass $M_\star \gtrsim 10^{7.5} \text{M}_\odot$, such relation shows little evolution from $z = 6$ to $z = 4$. At $z = 4$, the extension of the relation at $M_\star \lesssim 10^{6.5} \text{M}_\odot$ mark the presence of satellites forming in pre-enriched environments.

2. At $z = 6$ ($z = 4$) metals not locked in galaxies are distributed in the CGM/IGM/voids with the following mass fractions: 6%/4%/1% (3%/2%/1%).

3. Given the prevailing thermodynamical/ionization conditions of the enriched gas, C IV QSO spectroscopy can only probe up to $\approx 5\%$ of the total produced carbon. However, metal absorption lines are very effective tools to study reionization.

4. Analogously to the mass-metallicity relation for star forming regions, at $z = 4$ a $\Delta - Z$ relation is in place for the IGM/CGM. This is relation is due to the self-similarity of the radial density profiles.

5. Our $\text{EW}_{\text{HI}}$ analytical model (calibrated at $z = 4$) successfully reproduces CGM/IGM observations both at $z = 0$ (Liang&Chen 2014) and at $z = 2$ (Steidel et al. 2010), suggesting that the density profiles evolve very weakly with redshift.
